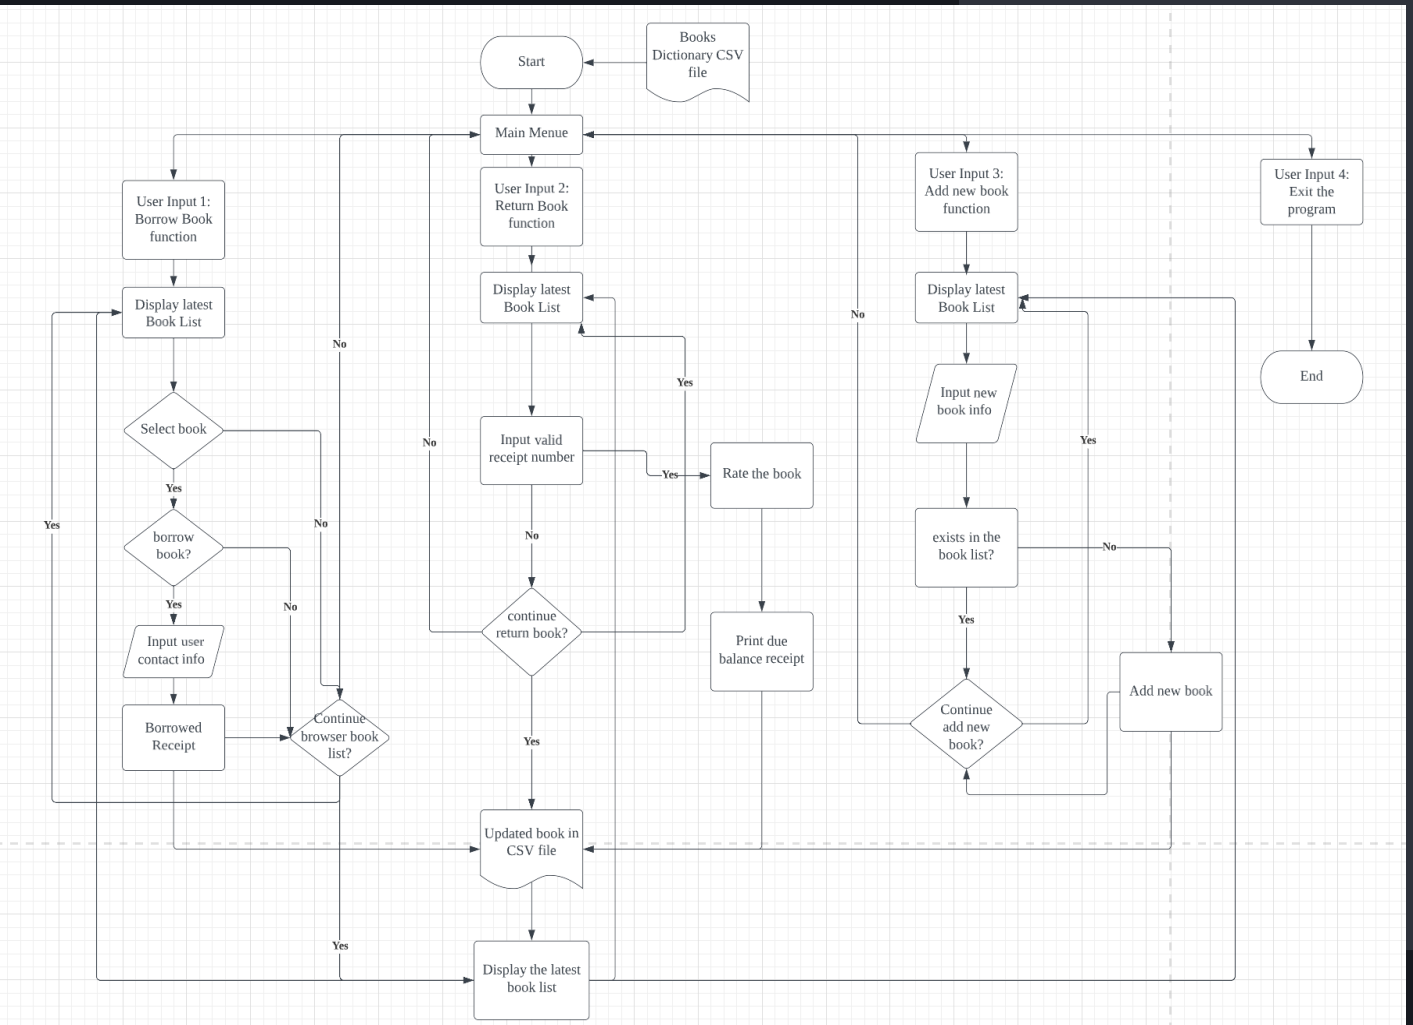
{Online Book Rental Store

T1A3 - Terminal Application

< Luying Han >

}



{Structure}

Online Book Rental Store app is a convenient terminal application that allows customers to repeatedly view the book listing, rent books, return books, and add books after starting to use the application.

Main Menu:

1. Borrow a book
2. Return a book
3. Add a new book
4. Exit the program

Main Menu

Display a menu of options to the user, and prompts them to enter a number corresponding to their desired action

Prompt_yes_no function used to control if user would like continue review the book list

Yes- continue the loop
No – exit browsing and return to main menu

```
# obtain user input1
if user_choice == "1":
    # def execute_user_choice_1(books):
    while True:
        display_books(books)
        selected_book = select_book(books)
        # if client select and confirm to borrow o book, update the book list
        if selected_book is not None:
            if borrow_book(selected_book) is not None:
                write_db(books, csv_file)

```

Borrow Book Feature

This feature allows users to iterate borrow a book online.

Display book function

It imports the 'PrettyTable' module to create a well-organized and easily readable table to present the book information stored in a CSV document to customers.
It first defines the column headers. Next, the program iterates through a list of books, appending the data of each book as a row to the table. Finally, the program prints out the entire table containing all book details, making it simple for customers to comprehend the availability of each book.

Borrow Book Feature

Select book function

1. Prompt user to input a 3-digital unique book id
2. List comprehension to create a new list that contains all books that matching the input id

```
# define a function for selected book
def select_book(books):
    # This function prompts the user to select a book from the given list of books
    # and returns the details of the selected book.
    while True:
        book_id = input(f"\n{fg(122)}Please enter the book ID you are interested: {attr(0)}")
        if not book_id.isdigit() or len(book_id) != 3:
            print(f"\n{fg(226)}Sorry, the book ID you have entered is not valid, please enter a valid 3-digit integer ID. {attr(0)}")
        else:
            break

    selected_book = [item for item in books if item["id"] == book_id]
    if len(selected_book) == 0:
        print(f"\n{fg(226)}Sorry, the book ID you have entered is not list in our online store. If you would like to add a new book, please press option 3. {attr(0)}")
        return

    selected_book = selected_book[0]
    if selected_book["status"] == "unavailable":
        if selected_book["due_date"] == "unavailable":
            print(f"\n{fg(226)}Sorry, the book will be add to our online store later, please check it after 7 days.")
        else:
            now = datetime.datetime.now()
            time_diff = datetime.datetime.strptime(
                selected_book["due_date"], "%Y-%m-%d").date() - now.date()
            print(f"\n{fg(226)}Sorry, the book is unavailable for rental currently. It will be available from {selected_book['due_date']}, {time_diff.days} days from today. {attr(0)}")
        return

    return selected_book
```

Borrow book function

Updates the information of select book and prints a receipt number for the transaction

Prompt user input their personal information using regex format

Generate unique receipt number

```python
def borrow_book(selected_book):
    # This function updates the information of the selected book and
    # print a receipt number for the transaction.

    if prompt_yes_or_no(f"\n{fg(229)}The book is currently available, do you want to borrow this book? (y/n): {attr(0)}"):

        print(f"\n{fg(122)}Please enter your personal information to complete the transaction.{attr(0)}")

Return Book Feature

The function uses loops and input functions to get the receipt number for returning the book from the customer.

If the receipt number exists in the book list, the function updates the relevant book information

Prompts the customer to rate the book and updates the book's average rating based on the current rating value

Display the remaining balance table

```python
while True:
    # error handling for invalid input
    try:
        return_receipt_number = int(input(f"\n{fg(122)}Please enter your receipt number:  {attr(0)}"))
        if return_receipt_number <= 0:
            print(f"\n{fg(229)}Please enter a positive integer. {attr(0)}")
            continue
        # check if the receipt number is in the book list
        for book in books:
            if book["receipt_number"] == int(return_receipt_number):
                print(f"\n{fg(226)}Thank you for returning {book['name']}. {attr(0)}")
                while True:
                    # rate the book and update the book rate information
                    try:
                        current_book_rate = float(input(f"\n{fg(122)}Please rate the book you have borrowed:  {attr(0)}"))
                        if current_book_rate < 1 or current_book_rate > 5:
                            raise ValueError
                    except ValueError:
                        print(f"\n{fg(229)}Invalid input. Please enter a non-zero number (from 1-5)")
                    else:
                        average_rate = (book["book_rate"] + current_book_rate)/2

                        book["book_rate"] = float(format(average_rate, '.1f'))

Add Book Feature

Function finds the maximum book ID from the book list.

It prompts the user to enter the information for the new book, including the book name and author name.

Uses a loop to check if the new book name already exists in the book list.

Exists – raise value error
Doesn't exists – add new book

```python
def add_book(books):
    print(f"\n{fg(122)}Please enter the following information to add a book: {attr(0)}")

    # add id from book list

    max_id = max(int(book["id"]) for book in books)

    try:
        book_name = validate_book_name()
        book_author = validate_author_name()
        for book in books:
            if book["name"].lower() == book_name.lower():
                raise ValueError(f"\nBook '{book_name}' already exists in the list.")

        # create a new book dictionary
        new_book = {}
        new_book["id"] = str(max_id + 1).zfill(3)
        new_book["name"] = book_name
        new_book["author"] = book_author
        new_book["rental_price"] = 0.0
        new_book["status"] = "unavailable"
        new_book["due_date"] = "unavailable"      You, yesterday • add test case
        new_book["book_rate"] = 0.0
        new_book["receipt_number"] = 0

        books.append(new_book)
        print(f"{fg(123)}{attr('bold')}\n{book_name} has been added to the list and will become available in 7 days.{attr(0)}")

    except ValueError as e:
        print(f"{fg(229)}{str(e)}{attr(0)}")
